- How to test whether two finite automata are equivalent?
- How to minimize a finite automaton?

1. Equivalence of Finite Automata

- Equivalence of States (\equiv)

- Distinguishable States (\neq)

- Table-Filling Algorithm

- Equivalence of Finite Automata

 - Examples

2. Minimization of Finite Automata

- Minimization Algorithm

 - Examples

- Proof of Minimum-State DFA

- Are the following two DFA **equivalent** (i.e., $L(D_0) = L(D_1)$)?

- Yes, because $L(D_0) = L(D_1) = \{wb \mid w \in \{a, b\}^*\}$.
- We first define the **equivalence of states** and utilize it to test the **equivalence of DFA**.

Definition (Equivalence of States (\equiv))

For a given DFA D , q_i is **equivalent** to q_j (i.e., $q_i \equiv q_j$) if and only if

$$\forall w \in \Sigma^*. \delta^*(q_i, w) \in F \iff \delta^*(q_j, w) \in F$$

However, it is difficult to make it as an algorithm. Let's consider $q_i \not\equiv q_j$:

$$q_i \not\equiv q_j \iff \exists w \in \Sigma^*. (\delta^*(q_i, w) \in F \iff \delta^*(q_j, w) \notin F)$$

We can *inductively* test q_i is **distinguishable** with q_j (i.e., $q_i \neq q_j$):

- (Basis Case) $w = \epsilon$

- (Induction Case) $w = ax$

$$\begin{aligned}
 &\exists a \in \Sigma. \exists w \in \Sigma^*. (\delta^*(q_i, aw) \in F \iff \delta^*(q_j, aw) \notin F) \\
 &\iff \exists a \in \Sigma. \exists w \in \Sigma^*. (\delta^*(\delta(q_i, a), w) \in F \iff \delta^*(\delta(q_j, a), w) \notin F) \\
 &\iff \exists a \in \Sigma. \delta(q_i, a) \neq \delta(q_j, a)
 \end{aligned}$$

Definition (Distinguishable States (\neq))

For a given DFA D , q_i is **distinguishable** with q_j (i.e., $q_i \neq q_j$) if and only if

- (Basis Case) $q_i \in F \iff q_j \notin F$.
- (Induction Case) $\exists a \in \Sigma. \delta(q_i, a) \neq \delta(q_j, a)$.

$$q_2 \neq q_4$$

$$(\because q_2 \in F \wedge q_4 \notin F)$$

$$q_1 \neq q_3$$

$$(\because \delta(q_1, a) = q_2 \neq q_4 = \delta(q_3, a))$$

$$q_0 \neq q_4$$

$$(\because \delta(q_0, b) = q_3 \neq q_1 = \delta(q_4, b))$$

q	a	b
→ q0	q1	q3
q1	q2	q1
* q2	q2	q2
q3	q4	q3
q4	q2	q1
q5	q4	q2

(Basis case) $w = \epsilon$.

$$q_i \in F \iff q_j \notin F$$

(Induction case) $w = ax$.

$$\exists a \in \Sigma. \delta(q_i, a) \neq \delta(q_j, a)$$

q	a	b
→ q0	q1	q3
q1	q2	q1
* q2	q2	q2
q3	q4	q3
q4	q2	q1
q5	q4	q2

(Basis case) $w = \epsilon$.

$$q_i \in F \iff q_j \notin F$$

(Induction case) $w = ax$.

$$\exists a \in \Sigma. \delta(q_i, a) \not\equiv \delta(q_j, a)$$

q1	x				
q2	x	x			
q3		x	x		
q4	x		x	x	
q5	x	x	x	x	x
	q0	q1	q2	q3	q4

$$q_0 \equiv q_3 \wedge q_1 \equiv q_4$$

Theorem (Equivalence of Finite Automata)

Consider two DFA $D = (Q, \Sigma, \delta, q_0, F)$ and $D' = (Q', \Sigma, \delta', q'_0, F')$

$$L(D) = L(D') \iff q_0 \equiv q'_0$$

in a DFA $D'' = (Q \uplus Q', \Sigma, \delta'', q_0, F \uplus F')$ where

$$\forall q'' \in Q \uplus Q'. \delta''(q, a) = \begin{cases} \delta(q'', a) & q'' \in Q \\ \delta'(q'', a) & q'' \in Q' \end{cases}$$

Proof) By the definition of equivalence of states, we have

$$\begin{aligned} L(D) = L(D') &\iff \forall w \in \Sigma^*. (D \text{ accepts } w \iff D' \text{ accepts } w) \\ &\iff \forall w \in \Sigma^*. (\delta^*(q_0, w) \in F \iff \delta'^*(q'_0, w) \in F') \\ &\iff \forall w \in \Sigma^*. (\delta''^*(q_0, w) \in F \cup F' \iff \delta''^*(q'_0, w) \in F \cup F') \\ &\iff q_0 \equiv q'_0 \text{ in } D'' \end{aligned}$$

Let's test the equivalence of D_2 and D_3 :

Let's perform the **table-filling algorithm**:

q_1	X			
q_2		X		
q_3		X		
q_4	X		X	X
	q_0	q_1	q_2	q_3

- $q_0 \equiv q_2 \equiv q_3$
- $q_1 \equiv q_4$

$$q_0 \equiv q_2 \implies L(D_0) = L(D_1) = \{wb \mid w \in \{a, b\}^*\}$$

Let's test the equivalence of D_0 and D_1 :

Let's perform the **table-filling algorithm**:

q_1	x							
q_2	x	x						
q_3		x	x					
q_4	x		x	x				
q_5	x	x	x	x	x			
q_6	x	x	x	x	x	x		
q_7	x		x	x		x	x	
q_8	x	x		x	x	x	x	x
	q_0	q_1	q_2	q_3	q_4	q_5	q_6	q_7

- $q_0 \equiv q_3$
- $q_1 \equiv q_4 \equiv q_7$
- $q_2 \equiv q_8$
- q_5
- q_6

$$q_0 \not\equiv q_6 \implies L(D_2) \neq L(D_3) \quad (\because ba \notin L(D_2) \text{ but } ba \in L(D_3))$$

- Is it possible to **minimize** a DFA?

- Yes, let's utilize **equivalence classes** Q/\equiv of states defined with \equiv .
- Note that \equiv is an **equivalence relation**:
 - reflexive: $\forall q \in Q. q \equiv q$
 - symmetric: $\forall q, q' \in Q. q \equiv q' \Leftrightarrow q' \equiv q$
 - transitive: $\forall q, q', q'' \in Q. q \equiv q' \wedge q' \equiv q'' \Leftrightarrow q \equiv q''$

For a given DFA $D = (Q, \sigma, \delta, q_0, F)$, the **minimization** algorithm is:

- 1 Remove all **unreachable states** from the initial state q_0 .
- 2 Partition the remaining states into **equivalence classes**:

$$Q/{\equiv} = \{[q]_{\equiv} \mid q \in Q\}$$

where the **equivalence class** of a state q is defined as:

$$[q]_{\equiv} = \{q' \in Q \mid q \equiv q'\}$$

- 3 Construct a new DFA $D/{\equiv} = (Q/{\equiv}, \Sigma, \delta/{\equiv}, [q_0]_{\equiv}, F/{\equiv})$ where

- $\delta/{\equiv} : Q/{\equiv} \times \Sigma \rightarrow Q/{\equiv}$ is defined by:

$$\forall q \in Q. \forall a \in \Sigma. \delta/{\equiv}([q]_{\equiv}, a) = [\delta(q, a)]_{\equiv}$$

(We can prove $\forall q', q'' \in [q]_{\equiv}. \forall a \in \Sigma. [\delta_{\equiv}(q', a)]_{\equiv} = [\delta_{\equiv}(q'', a)]_{\equiv}$.)

- $F/{\equiv} = \{[q]_{\equiv} \mid q \in F\}$

① Remove unreachable states

② Partition the states into Q/\equiv

$$Q/\equiv = \{ \{q_0, q_1\}, (\because q_0 \equiv q_1) \{q_2\}, \}$$

③ Construct a new DFA D/\equiv

① Remove unreachable states

② Partition the states into Q/\equiv

$$Q/\equiv = \left\{ \begin{array}{l} \{q_0, q_3\}, \quad (\because q_0 \equiv q_3) \\ \{q_1, q_4\}, \quad (\because q_1 \equiv q_4) \\ \{q_2\}, \\ \end{array} \right\}$$

③ Construct a new DFA D/\equiv

Theorem (Minimum-State DFA)

For a given DFA $D = (Q, \Sigma, \delta, q_0, F)$, its minimized DFA D/\equiv is a **minimum-state DFA** of D .

(i.e., \nexists DFA $D' = (Q', \Sigma, \delta', q'_0, F')$. s.t. $L(D') = L(D) \wedge |Q'| < |Q/\equiv|$).

- Assume that \exists DFA D' . Then, $m < n$ when $m = |Q'|$ and $n = |Q/\equiv|$.
- For any state $q \in Q/\equiv$, we can find a state $q' \in Q'$ such that $q \equiv q'$.
 - $\forall q \in Q/\equiv. \exists w = a_1 \cdots a_k$. s.t. $\delta/\equiv(q_0, w) = q$. ($\because q$ is reachable.)
 - Let $q' = \delta'(q'_0, w)$. Then, $\delta'^*(q'_0, a_0 \cdots a_i) \equiv \delta/\equiv^*(q_0, a_0 \cdots a_i)$ for all $0 \leq i \leq k$.
 - **(Basis Case)** $\delta'^*(q'_0, \epsilon) = q'_0 \equiv q_0 = \delta/\equiv^*(q_0, \epsilon)$
 - **(Induction Case)** Assume $\delta'^*(q'_0, a_0 \cdots a_i) \not\equiv \delta/\equiv^*(q_0, a_0 \cdots a_i)$. Then, by the definition of distinguishable states, $\delta'^*(q'_0, a_0 \cdots a_{i-1}) \not\equiv \delta/\equiv^*(q_0, a_0 \cdots a_{i-1})$. But, it contradicts the induction hypothesis.
- By Pigeonhole Principle, $\exists q_i \neq q_j \in Q/\equiv. \exists q' \in Q'. q_i \equiv q' \wedge q_j \equiv q'$.
- It means that $q_i \equiv q_j$. However, it contradicts that Q/\equiv is partitioned into equivalence classes of states. □
