Acceptance by Empty Stacks

Pushdown Automata

A pushdown automaton (PDA) is an ϵ -NFA with a stack:

- In FA, the next state is determined by the current state and symbol.
- In PDA, the next state is determined by the current state, symbol, and the top symbol of the stack.

Definition of Pushdown Automata

Definition (Pushdown Automata)

A pushdown automaton (PDA) is a 7-tuple:

$$P = (Q, \Sigma, \Gamma, \delta, q_0, Z, F)$$

where

- Q is a finite set of states
- Σ is a finite set of symbols
- Γ is a finite set of stack alphabets
- $\delta: Q \times (\Sigma \cup \{\epsilon\}) \times \Gamma \to \mathcal{P}(Q \times \Gamma^*)$ is a transition function
- $q_0 \in Q$ is the initial state
- $Z \in \Gamma$ is the **initial stack alphabet** (the stack is initially Z)
- $F \subset Q$ is a set of final states

Definition of Pushdown Automata - Example

$$P = (\{q_0, q_1, q_2\}, \{a, b\}, \{Z, A\}, \delta, q_0, Z, \{q_2\})$$

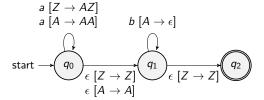

where

$$\begin{array}{lll} \delta(q_0, \mathbf{a}, Z) & = & \{(q_0, AZ)\} \\ \delta(q_0, \mathbf{a}, A) & = & \{(q_0, AA)\} \\ \delta(q_0, \mathbf{b}, Z) & = & \varnothing \\ \delta(q_0, \mathbf{b}, A) & = & \varnothing \\ \delta(q_0, \epsilon, Z) & = & \{(q_1, Z)\} \\ \delta(q_0, \epsilon, A) & = & \{(q_1, A)\} \\ \delta(q_1, \mathbf{a}, Z) & = & \varnothing \\ \delta(q_1, \mathbf{a}, A) & = & \varnothing \\ \delta(q_1, \mathbf{b}, Z) & = & \varnothing \\ \delta(q_1, \mathbf{b}, A) & = & \{(q_1, \epsilon)\} \\ \delta(q_1, \epsilon, Z) & = & \{(q_2, Z)\} \\ \delta(q_1, \epsilon, A) & = & \varnothing \\ \delta(q_2, _, _) & = & \varnothing \end{array}$$

Transition Diagram

$$P = (\{q_0, q_1, q_2\}, \{a, b\}, \{Z, A\}, \delta, q_0, Z, \{q_2\})$$

For example,

$$\delta(q_0, a, Z) = \{(q_0, AZ)\}\$$

 $\delta(q_0, a, A) = \{(q_0, AA)\}\$

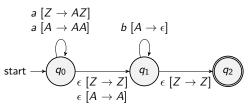

$$P = (Q, \Sigma, \Gamma, \delta, q_0, Z, F)$$
$$\delta : Q \times (\Sigma \cup \{\epsilon\}) \times \Gamma \to \mathcal{P}(Q \times \Gamma^*)$$

```
// The type definitions of states and symbols
type State = Int
type Symbol = Char
type Word = String
type Alphabet = Char
// The definition of PDA
case class PDA(
  states: Set[State].
  symbols: Set[Symbol],
  alphabets: Set[Alphabet],
  trans: Map[(State, Option[Symbol], Alphabet), Set[(State, List[Alphabet])]],
  initState: State,
  initAlphabet: Alphabet,
  finalStates: Set[State],
```

Pushdown Automata in Scala – Example

```
// An example of PDA
val pda1: PDA = PDA(
 states = Set(0, 1, 2), symbols = Set('a', 'b'),
 alphabets = Set('Z', 'A'), trans
                                         = Map(
   (0, Some('a'), 'Z') -> Set((0, List('A', 'Z'))),
   (0, Some('a'), 'A') -> Set((0, List('A', 'A'))),
   (0, None, 'Z') -> Set((1, List('Z'))),
   (0, None, 'A') -> Set((1, List('A'))),
   (1, Some('b'), 'A') -> Set((1, List())),
   (1, None, 'Z') -> Set((2, List('Z'))),
 ).withDefaultValue(Set()),
                                  initAlphabet = 'Z',
 initState = 0.
 finalStates = Set(2),
```

Configurations and One-Step Moves

Definition (Configurations of PDA)

A configuration of a PDA P is a triple (q, w, α) where

- $q \in Q$: the current state
- $w \in \Sigma^*$: the remaining word
- $\alpha \in \Gamma^*$: the current state of the stack

Definition (One-Step Moves of PDA)

A **one-step move** (\vdash) of a PDA P is a transition from a configuration to another configuration:

$$(q, aw, A\beta) \vdash (p, w, \alpha\beta)$$
 if $(p, \alpha) \in \delta(q, a, A)$
 $(q, w, A\beta) \vdash (p, w, \alpha\beta)$ if $(p, \alpha) \in \delta(q, \epsilon, A)$

Configurations and One-Step Moves

$$egin{array}{lll} (q_0,\mathtt{ab},Z) & dash & (q_0,\mathtt{b},AZ) & (\ddots (q_0,AZ) \in \delta(q_0,\mathtt{a},Z)) \\ & dash & (q_1,\mathtt{b},AZ) & (\ddots (q_1,A) \in \delta(q_0,\epsilon,A)) \\ & dash & (\ddots (q_1,A) \in \delta(q_0,\epsilon,A)) \\ & dash & (\ddots (q_1,\epsilon) \in \delta(q_1,\mathtt{b},A)) \\ & dash & (\ddots (q_2,Z) \in \delta(q_1,\epsilon,Z)) \end{array}$$

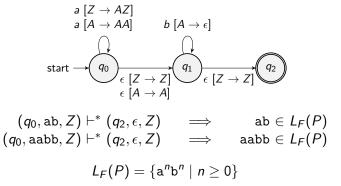

Acceptance by Final States

Definition (Acceptance by Final States)

For a given PDA $P = (Q, \Sigma, \Gamma, \delta, q_0, Z, F)$, the language accepted by **final** states is defined as:

$$L_F(P) = \{ w \in \Sigma^* \mid (q_0, w, Z) \vdash^* (q, \epsilon, \alpha) \text{ for some } q \in F, \alpha \in \Gamma^* \}$$

$$L_F(P) = \{ w \in \Sigma^* \mid (q_0, w, Z) \vdash^* (q, \epsilon, \alpha) \text{ for some } q \in F, \alpha \in \Gamma^* \}$$

```
// The type definition of configurations
type Config = (State, Word, List[Alphabet])
// Configurations reachable from the initial configuration by one-step moves
def reachableConfig(pda: PDA)(word: Word): Set[Config] = ...
// Acceptance by final states
def acceptByFinalState(pda: PDA)(word: Word): Boolean =
 reachableConfig(pda)(word).exists(config => {
   val (q, w, xs) = config
   w.isEmpty && pda.finalStates.contains(q)
 })
acceptByFinalState(pda1)("ab") // true
acceptByFinalState(pda1)("aba") // false
acceptByFinalState(pda1)("aabb") // true
acceptByEmptyStack(pda1)("abab") // false
```

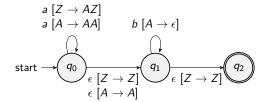

Acceptance by Empty Stacks

Definition (Acceptance by Empty Stacks)

For a given PDA $P = (Q, \Sigma, \Gamma, \delta, q_0, Z, F)$, the language accepted by **empty stacks** is defined as:

$$L_E(P) = \{ w \in \Sigma^* \mid (q_0, w, Z) \vdash^* (q, \epsilon, \epsilon) \text{ for some } q \in Q \}$$

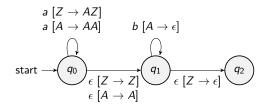

Acceptance by Empty Stacks

Definition (Acceptance by Empty Stacks)

For a given PDA $P = (Q, \Sigma, \Gamma, \delta, q_0, Z, F)$, the language accepted by **empty stacks** is defined as:

$$L_E(P) = \{ w \in \Sigma^* \mid (q_0, w, Z) \vdash^* (q, \epsilon, \epsilon) \text{ for some } q \in Q \}$$

$$(q_0, \mathtt{ab}, Z) \vdash^* (q_2, \epsilon, \epsilon) \implies \mathtt{ab} \in L_E(P)$$

$$L_E(P) = \{a^n b^n \mid n \ge 0\}$$

$$L_E(P) = \{ w \in \Sigma^* \mid (q_0, w, Z) \vdash^* (q, \epsilon, \epsilon) \text{ for some } q \in Q \}$$

```
// The type definition of configurations
type Config = (State, Word, List[Alphabet])
// Configurations reachable from the initial configuration by one-step moves
def reachableConfig(pda: PDA)(word: Word): Set[Config] = ...
// Acceptance by empty stacks
def acceptByEmptyStack(pda: PDA)(word: Word): Boolean =
 reachableConfig(pda)(word).exists(config => {
   val (q, w, xs) = config
   w.isEmpty && xs.isEmpty
 })
// Another example of PDA
val pda2: PDA = ...
acceptByEmptyStack(pda2)("ab") // true
acceptByEmptyStack(pda2)("aba") // false
acceptByEmptyStack(pda2)("aabb") // true
acceptByEmptyStack(pda2)("abab") // false
```
